0.1 ei.RxC: Hierarchical Multinomial-Dirichlet Ecological Inference Model for $R \times C$ Tables

Given n contingency tables, each with observed marginals (column and row totals), ecological inference (EI) estimates the internal cell values in each table. The hierarchical Multinomial-Dirichlet model estimates cell counts in $R \times C$ tables. The model is implemented using a nonlinear least squares approximation and, with bootstrapping for standard errors, had good frequentist properties.

Syntax

Inputs

- T0, T1, T2,..., TC: numeric vectors (either counts, or proportions that sum to one for each row) containing the column margins of the units to be analyzed.
- X0, X1, X2,...,XR: numeric vectors (either counts, or proportions that sum to one for each row) containing the row margins of the units to be analyzed.
- covar: (optional) a covariate that varies across tables, specified as covar = ~ Z1, for example. (The model only accepts one covariate.)

Examples

1. Basic examples: No covariate Attaching the example dataset:

```
> data(Weimar)
```

Estimating the model:

```
> z.out <- zelig(cbind(Nazi, Government, Communists, FarRight,
+ Other) ~ shareunemployed + shareblue + sharewhite + shareself +
+ sharedomestic, model = "ei.RxC", data = Weimar)
> summary(z.out)
```

Estimate fractions of different social groups that support political parties:

```
> s.out <- sim(z.out, num = 10)
```

Summarizing fractions of different social groups that support political parties:

- > summary(s.out)
- 2. Example of covariates being present in the model

Using the example dataset Weimar and estimating the model

```
> z.out <- zelig(cbind(Nazi, Government, Communists, FarRight,
+ Other) ~ shareunemployed + shareblue + sharewhite + shareself +
+ sharedomestic, covar = ~shareprotestants, model = "ei.RxC",
+ data = Weimar)
> summary(z.out)
```

Set the covariate to its default (mean/median) value

```
> x.out <- setx(z.out)</pre>
```

Estimate fractions of different social groups that support political parties:

```
> s.out <- sim(z.out, num = 100)
```

Summarizing fractions of different social groups that support political parties:

```
> s.out <- summary(s.out)</pre>
```

Model

Consider the following 5×5 contingency table for the voting patterns in Weimar Germany. For each geographical unit i (i = 1, ..., p), the marginals $T_{1i}, ..., T_{Ci}, X_{1i}, ..., X_{Ri}$ are known for each of the p electoral precincts, and we would like to estimate ($\beta_i^{rc}, r = 1, ..., R, c = 1, ..., C - 1$) which are the fractions of people in social class r who vote for party c, for all r and c.

	Nazi	Government	Communists	Far Right	Other	
Unemployed	β_{11}^i	eta^i_{12}	β_{13}^i	β_{14}^i	$1 - \sum_{c=1}^{4} \beta_{1c}^{i}$	X_1^i
Blue	eta^i_{21}	eta^i_{22}	eta^i_{23}	eta^i_{24}	$1 - \sum_{c=1}^{4} \beta_{2c}^{i}$	X_2^i
White	β_{31}^i	eta^i_{32}	eta^i_{33}	eta^i_{34}	$1 - \sum_{c=1}^{4} \beta_{3c}^{i}$	X_3^i
Self	β_{41}^i	eta^i_{42}	eta^i_{43}	eta_{44}^i	$1 - \sum_{c=1}^{4} \beta_{4c}^{i}$	X_4^i
Domestic	β_{51}^i	eta^i_{52}	eta^i_{53}	eta^i_{54}	$1 - \sum_{c=1}^{4} \beta_{5c}^{i}$	X_5^i
	T_{1i}	T_{2i}	T_{3i}	T_{4i}	$1 - \sum_{c=1}^{4} \beta_{ci}$	

The marginal values $X_{1i}, \ldots, X_{Ri}, T_{1i}, \ldots, T_{Ci}$ may be observed as counts or fractions.

Let $T_i' = (T'_{1i}, T'_{2i}, \dots, T'_{Ci})$ be the number of voting age persons who turn out to vote for different parties. There are three levels of hierarchy in the Multinomial-Dirichlet EI model. At the first stage, we model the data as:

• The stochastic component is described T'_i which follows a multinomial distribution:

$$T_i' \sim \text{Multinomial}(\Theta_{1i}, \dots, \Theta_{Ci})$$

• The systematic components are

$$\Theta_{ci} = \sum_{r=1}^{R} \beta_{rc}^{i} X_{ri} \quad \text{for} \quad c = 1, \dots, C$$

At the second stage, we use an optional covariate to model Θ_{ci} 's and β_{qrc}^i :

• The stochastic component is described by $\beta_r^i = (\beta_{r1}, \beta_{r2}, \dots, \beta_{r,C-1})$ for $i = 1, \dots, p$ and $r = 1, \dots, R$, which follows a Dirichlet distribution:

$$\beta_r^i \sim \text{Dirichlet}(\alpha_{r1}^i, \dots, \alpha_{rc}^i)$$

• The *systematic components* are

$$\alpha_{rc}^{i} = \frac{d_{r}exp(\gamma_{rc} + \delta_{rc}Z_{i})}{d_{r}(1 + \sum_{j=1}^{C-1} exp(\gamma_{rj} + \delta_{rj}Z_{i}))} = \frac{exp(\gamma_{rc} + \delta_{rc}Z_{i})}{1 + \sum_{j=1}^{C-1} exp(\gamma_{rj} + \delta_{rj}Z_{i})}$$

for
$$i = 1, ..., p, r = 1, ..., R$$
, and $c = 1, ..., C - 1$.

In the third stage, we assume that the regression parameters (the γ_{rc} 's and δ_{rc} 's) are a priori independent, and put a flat prior on these regression parameters. The parameters d_r for $r = 1, \ldots, R$ are assumed to follow exponential distributions with mean $\frac{1}{\lambda}$.

Output Values

The output of each Zelig command contains useful information which you may view. For example, if you run

then you may examine the available information in z.out by using names(z.out). For example,

- From the zelig() output object z.out\$coefficients are the estimates of γ_{ij} (and also δ_{ij} , if covariates are present). The parameters are returned as a single vector of length $R \times (C-1)$. If there is a covariate, δ is concatenated to it.
- From the sim() output object, you may extract the parameters β_{ij} corresponding to the estimated fractions of different social groups that support different political parties, by using s.outqi\$ev. For each precinct, that will be a matrix with dimensions: simulations $\times R \times C$.

summary(s.out) will give you the nationwide aggregate parameters.
