0.1 describe: Describe a model's systematic and stochastic parameters

Description

In order to use parse.formula(), parse.par(), and the model.*.multiple() commands, you must write a describe.mymodel() function where mymodel is the name of your modeling function. (Hence, if your function is called normal.regression(), you need to write a describe.normal.regression() function.) Note that describe() is not a generic function, but is called by parse.formula(..., model = "mymodel") using a combination of paste() and exists(). You will never need to call describe.mymodel() directly, since it will be called from parse.formula() as that function checks the user-input formula or list of formulas.

Syntax

describe.mymodel()

Arguments

The describe.mymodel() function takes no arguments.

Output Values

The describe.mymodel() function returns a list with the following information:

- category: a character string, consisting of one of the following:
 - "continuous": the dependent variable is continuous, numeric, and unbounded (e.g., normal regression), but may be censored with an associated censoring indicator (e.g., tobit regression).
 - "dichotomous": the dependent variable takes two discrete integer values, usually 0 and 1 (e.g., logistic regression).
 - "ordinal": the dependent variable is an ordered factor response, taking 3 or more discrete values which are arranged in an ascending or descending manner (e.g., ordered logistic regression).
 - "multinomial": the dependent variable is an unordered factor response, taking 3 or more discrete values which are arranged in no particular order (e.g., multinomial logistic regression).
 - "count": the dependent variable takes integer values greater than or equal to 0 (e.g., Poisson regression).

- "bounded": the dependent variable is a continuous numeric variable, that is restricted (bounded within) some range (e.g., $(0, \infty)$). The variable may also be censored either on the left and/or right side, with an associated censoring indicator (e.g., Weibull regression).
- "mixed": the dependent variables are a mix of the above categories (usually applies to multiple equation models).

Selecting the category is particularly important since it sets certain interface parameters for the entire GUI.

- package: (optional) a list with the following elements
 - name: a characters string with the name of the package containing the mymodel() function.
 - version: the minimum version number that works with Zelig.
 - CRAN: if the package is not hosted on CRAN mirrors, provide the URL here as a character string. You should be able to install your package from this URL using name, version, and CRAN:

```
install.packages(name, repos = CRAN, installWithVers = TRUE)
By default, CRAN = "http://cran.us.r-project.org/".
```

- parameters: For each systematic and stochastic parameter (or set of parameters) in your model, you should create a list (named after the parameters as given in your model's notation, e.g., mu, sigma, theta, etc.; not literally myparameter) with the following information:
 - equations: an integer number of equations for the parameter. For parameters that can take an undefined number of equations (for example in seemingly unrelated regression), use c(2, Inf) or c(2, 999) to indicate that the parameter can take a minimum of two equations up to a theoretically infinite number of equations.
 - tagsAllowed: a logical value (TRUE/FALSE) specifying whether a given parameter allows constraints. If there is only one equation for a parameter (for example, mu for the normal regression model has equations = 1), then tagsAllowed = FALSE by default. If there are two or more equations for the parameter (for example, mu for the bivariate probit model has equations = 2), then tagsAllowed = TRUE by default.
 - depVar: a logical value (TRUE/FALSE) specifying whether a parameter requires a corresponding dependent variable.

- expVar: a logical value (TRUE/FALSE) specifying whether a parameter allows explanatory variables. If depVar = TRUE and expVar = TRUE, we call the parameter a "systematic component" and parse.formula() will fail if formula(s) are not specified for this parameter. If depVar = FALSE and expVar = TRUE, the parameter is estimated as a scalar ancillary parameter, with default formula ~ 1, if the user does not specify a formula explicitly. If depVar = FALSE and expVar = FALSE, the parameter can only be estimated as a scalar ancillary parameter.
- specialFunction: (optional) a character string giving the name of a function that appears on the left-hand side of the formula. Options include "Surv", "cbind", and "as.factor".
- varInSpecial: (optional) a scalar or vector giving the number of variables taken by the specialFunction. For example, Surv() takes a minimum of 2 arguments, and a maximum of 4 arguments, which is represented as c(2, 4).

If you have more than one parameter (or set of parameters) in your model, you will need to produce a myparameter list for each one. See examples below for details.

Examples

For a Normal regression model with mean mu and scalar variance parameter sigma2, the minimal describe.*() function is as follows:

See Section ?? for full code to execute this model from scratch in R with Zelig.

Now consider a bivariate probit model with parameter vector mu and correlation parameter rho (which may or may not take explanatory variables). Since the bivariate probit function uses the pmvnorm() function from the mvtnorm library, we list this under package.

```
describe.bivariate.probit <- function() {
  category <- "dichotomous"
  package <- list(name = "mvtnorm",</pre>
```

```
version = "0.7")
 mu <- list(equations = 2,</pre>
                                              # Systematic component
              tagsAllowed = TRUE,
              depVar = TRUE,
              expVar = TRUE)
  rho <- list(equations = 1,</pre>
                                             # Optional systematic component
              tagsAllowed = FALSE,
                                             # Estimated as an ancillary
              depVar = FALSE,
                                                   parameter by default
              expVar = TRUE)
  pars <- list(mu = mu, rho = rho)</pre>
  list(category = category, package = package, parameters = pars)
}
See Section ?? for the full code to write this model from scratch in R with Zelig.
   For a multinomial logit model, which takes an undefined number of equations (corre-
sponding to each level in the response variable):
describe.multinomial.logit <- function() {</pre>
  category <- "multinomial"</pre>
  mu <- list(equations = c(1, Inf),</pre>
              tagsAllowed = TRUE,
              depVAR = TRUE,
              expVar = TRUE,
              specialFunction <- "as.factor",</pre>
              varInSpecial <- c(1, 1))</pre>
  list(category = category, parameters = list(mu = mu))
}
```

(This example does not have corresponding executable sample code.)
